# Nonabelian homotopical cohomology, higher fiber bundles with connection, and their $\sigma$-model QFTs 

January 14, 2009

#### Abstract

Nonabelian cohomology can be regarded as a generalization of group cohomology to the case where both the group itself as well as the coefficient object are allowed to be generalized to $\infty$-groupoids or even to general $\infty$-categories. Cocycles in nonabelian cohomology in particular represent higher principal bundles (gerbes) - possibly equivariant, possibly with connection - as well as the corresponding associated higher vector bundles.

We formulate nonabelian cohomology and its classification of fiber bundles in a general context of enriched homotopy theory, and discuss general issues such as lifting and extension problems. We list examples and applications with enrichment over higher categories which describe higher principal bundles and higher vector bundles, possibly equivariant, possibly with connection.

Building on this we propose, expanding on considerations in [15, 42, 6], a systematic $\infty$-functorial formalization of the $\sigma$-model quantum field theory associated with a given nonabelian cocycle regarded as the background field for a brane coupled to it. We define propagation in these $\sigma$-model QFTs and recover central aspects of groupoidification [1, 2].

In a series of examples we show how this formalization reproduces familiar structures in $\sigma$-models with finite target spaces such as Dijkgraaf-Witten theory and the Yetter model. Applications to $\sigma$-models with smooth target spaces is developed elsewhere [26].

## 1 Introduction

A $\sigma$-model should, quite generally, be an $n$-dimensional quantum field theory which is canonically associated with the geometric structure given by a connection on a bundle whose fibers are $n$-categories - for instance a (higher) gerbe with connection.
For example for $n=1$ a line bundle with connection over a Riemann manifold gives rise to the ordinary quantum mechanics of a charged particle. For $n=2$ a line bundle gerbe with connection over a Lie group $G$ gives rise to the 2-dimensional quantum field theory known as the WZW-model. For $n=3$ a Chern-Simons 2-gerbe with connection over $B G$ gives rise to Chern-Simons QFT.

The natural conceptual home of these higher connections appearing here is differential nonabelian cohomology [26], a joint generalization of sheaf cohomology, group cohomology and nonabelian group cohomology. One arrives at this general notion of cohomology for instance by first generalizing the coefficients of sheaf cohomology from complexes of abelian groups, via crossed complexes of groupoids and their equivalent $\infty$-groupoids [8], to general $\infty$-categories, and secondly by generalizing the domain spaces via orbifolds, hypercovers and their equivalent $\infty$-groupoids also to general $\infty$-categories. Therefore nonabelian cocycles are cocycles on $\infty$-categories with coefficients in $\infty$-categories. Moreover, when suitably interpreted such a cocycle is nothing but an $\infty$-functor from its domain to its coefficient object, hence a rather fundamental concept. In one way or other it is well known that such cocycles in particular classify fiber bundles - possibly equivariant - whose fibers are higher categories.

In a series of articles [3, 35, 36, 37] (see also [23]) it was shown for low $n$ that by internalizing this notion of $\infty$-functorial nonabelian cocycles from the category of plain sets into a category of generalized smooth spaces, it yields a good notion of generalized differential cohomology: if the domain $\infty$-category is taken to be the smooth fundamental $\infty$-groupoid of a smooth space, then smooth $\infty$-functors out of it provide a higher dimensional notion of parallel transport and characterize higher connections on higher fiber bundles.

Indeed, regarding an $\infty$-functorial cocycle as a parallel transport functor generally provides a useful heuristic for the sense in which generalized cocycles are nothing but $\infty$-functors from their domain to their coefficient object, even if there is no smooth structure and no connection around: the $\infty$-functorial cocycles characterizing for instance a fiber bundle is the fiber-assigning functor which to each point in base space assigns the fiber sitting over that point, to each morphism in base space (be it a jump along an orbifold action, or a jump between points in the fiber of a Cech cover, or indeed a smooth path in base space) the corresponding morphisms between the fibers over its endpoints, and similarly for higher morphisms.

From this perspective much can already be learned from and achieved in finite approximations to full smooth differential cocycles. A central example is Dijkgraaf-Witten theory as a finite version of Chern-Simons theory: while Chern-Simons theory is a $\sigma$-model governed by a differential 3 -cocycle on $B G$ - in the smooth context- usually addressed as the Chern-Simons 2-gerbe - Dijkgraaf-Witten theory is diagrammatically the same setup, but now internal to $\infty$-categories internal to Sets: the space $B G$ is replaced by the finite groupoid $\mathbf{B} G$ with one object and Hom-set the finite group $G$. So among other things, $\infty$-functorial nonabelian cohomology, which treats group cocycles and higher bundles/higher gerbes intrinsically on the same footing, gives a precise formalization of the way in which finite group models such as Dijkgraaf-Witten theory are related to their smooth cousins such as Chern-Simons theory.

For that reason it is worthwhile to study the $\infty$-functorial nonabelian cohomology perspective on finite group $\sigma$-models before adding the further technical complication of working internal to smooth spaces. While discussion of differential nonabelian cohomology in the context of smooth spaces is in preparation in [26], here we develop some concepts and their applications in the simpler context of plain sets.

In sections 3 and 5 we set up the central concepts which we use to formalize the notion of a $\sigma$-model associated with a (differential) nonabelian cocycle. In particular we formalize in this context the notion of higher sections and higher spaces of states as indicated in [15, 42], and generalize to corresponding notions of branes and bibranes [17]. In section 5 we then go through a list of examples and applications illustrating these concepts.

## 2 Enriched homotopy theory

There are two major well-developed 1-categorical tools for handling models for (directed) spaces and higher (directed) homotopies, i.e. for $\infty$ - or $\omega$-categories: these are enriched category theory and model category theory. A comprehensive treatment is obtained from the combination of the two, known as enriched homotopy theory or homotopy coherent category theory.

For enriched category theory we rely on the canonical textbook [20]. For homotopy theory we mainly make use of the seminal article [7] and hence mostly require less structure than in full model category theory. The systematic study of enriched homotopy theory is much younger: we adopt the point of view of [33], which follows the textbooks $[12,18]$.

In section 3 we consider higher fiber bundles - possibly equivariant, possibly with connection - in a generic homotopical context without comitting ourserves to a concrete model for $\infty$-categories or $\omega$-categories, aiming to come close to requiring a necessary minimum of structural prerequisites. The idea is to stipulate that an object $\mathbf{A}$ in a category of higher structures should be

1. a generalized space locally modeled on objects in a locally small category $S$;
2. and equipped with a consistent notion of homotopy between maps into it.

The first point we read as implying that $\mathbf{A}$ is characterized by maps of test-objects in $S$ into it, making it a presheaf on $S$. The second point then suggests that this presheaf takes values in a homotopical category $\mathcal{V}$ and that $S$ is $\mathcal{V}$-enriched such that there are $\mathcal{V}$-internal spaces of morphisms. The solution to this requirement suggested by [33] is to take $\mathcal{V}$ to be a closed monoidal homotopical category so that $\mathcal{C}:=\left[S^{\circ \mathrm{p}}, \mathcal{V}\right]$ is $\mathcal{V}$-enriched and becomes $\mathcal{V}$-enriched homotopical after choosing suitable local extensions of the weak equivalences in $\mathcal{V}$ to $\mathcal{C}$. The nice consequence of these natural assumptions is that the homotopy category $\mathrm{Ho}_{\mathcal{C}}$ of $\mathcal{C}$ is naturally Hov-enriched while itself homotopical in a $\mathcal{V}$-enriched sense and thus retains information about higher homotopies and their weak inverses. This should make it an accurate enriched 1-categorical model for an $\infty$-category of $\infty$-categories modeled on $S$.

Two complementary useful perspectives on objects in such homotopically enriched presheaf categories $\mathcal{C}$ are familiar: as generalized homotopical spaces and as $\infty$-stacks. For instance if $S=$ Diff is the site of smooth manifolds, then a higher structure probeable by mapping objects in $S$ into it may be a Lie groupoid A, a higher structure whose smoothness is modeled by how test-objects in Diff are mapped into it. By instead regarding the assignment to an object $X \in$ Diff of collections $[X, \mathbf{A}] \stackrel{\text { Yoneda }}{\sim} \mathbf{A}(X)$ of maps from $X$ into $\mathbf{A}$ as primary, it appears instead equivalently as the differentiable stack on $S$ presented by the Lie groupoid.

More generally, for the choice $\mathcal{V}:=$ SimplicialSets it is well known [41, 40] that the Hov-enriched homotopy category $\operatorname{Ho}_{\mathcal{C}}$ for $\mathcal{C}:=\left[S^{\circ \mathrm{p}}, \mathcal{V}\right]$ the $\mathcal{V}$-enriched category of simplicial presheaves (with weak equivalences the local weak equivalences of SimplicialSets) is an enriched 1-categorical model of $\infty$-stacks on $S$. In our examples and applications in section 4 we find it useful to choose for $\mathcal{V}$ categories of globular (instead of simplicial) $n$-categories equipped with the folk model structure [14, 9]; such as to make contact to results in [37]. The general considerations in section 3 are independent of all such choices of conrete realizations of $\mathcal{V}$ and $\mathcal{C}$.

## 3 Nonabelian homotopical cohomology

We place ourselves in the context of derived $\mathcal{V}$-enriched category theory for $\mathcal{V}$ a closed monoidal homotopical category and consider a $\mathcal{V}$-enriched homotopical category $\mathcal{C}$ as described in [33].

Recall (sections 15 and 16 in [33]) that this means that $\mathcal{V}$ is a category equipped with a choice of weak equivalences compatible with its closed monoidal structure, and in particular that on the Sets-enriched category $\mathcal{C}_{0}:=\mathcal{V}-\operatorname{Cat}(I, \mathcal{C})$ underlying the $\mathcal{V}$-enriched category $\mathcal{C}$ there is a $\mathcal{V}$-valued hom-functor hom : $\mathcal{C}_{0} \times \mathcal{C}_{0} \rightarrow \mathcal{V}$ compatible with the action of $\mathcal{V}$ on $\mathcal{C}$ by powers $[-,-]$ and by copowers $\otimes$ which determines
the $\mathcal{V}$-enrichment of $\mathcal{C}$ by $\mathcal{C}(\mathbf{X}, \mathbf{A}) \simeq \operatorname{hom}(\mathbf{X}, \mathbf{A})$ for all objects $\mathbf{Y}, \mathbf{A}$ in $\mathcal{C}_{0}$. Its right-derived functor $\mathbb{R}$ hom

similarly induces the $\mathrm{Ho}_{\mathcal{V}}$-enriched category $\mathrm{Ho}_{\mathcal{C}}$ whose underlying Sets-enriched category is the homotopy category $\mathrm{Ho}_{\mathcal{C}_{0}}$ of $\mathcal{C}_{0}$ (proposition 16.2 in [33]).

In such a setup cohomology identifies with the hom-objects in the homotopy categories, and algorithms for computation of cohomology are algorithms for computation of the right derived (internal) hom-functors:

Definition 3.1 (cohomology) For $\mathcal{C}$ a $\mathcal{V}$-enriched homotopical category of the form $\left[S^{\circ \mathrm{p}}, \mathcal{V}\right]$ or $\operatorname{Sh}(S, \mathcal{V})$, we say for $\mathbf{A}$ any object of $\mathcal{C}$ and $X$ a representable object that $H(X, \mathbf{A}):=\operatorname{Ho}_{\mathcal{C}_{0}}(X, \mathbf{A})$ is the cohomology of $X$ with coefficients in $\mathbf{A}$. The generalized elements $c: I \rightarrow Z(X, \mathbf{A})$ of the $\mathcal{V}$-object $Z(X, \mathbf{A}):=\operatorname{Ho}_{\mathcal{C}}(X, \mathbf{A})$ are the cocycles on $X$ with coefficients in $\mathbf{A}$. Homotopies between these are the coboundaries.

More generally $\operatorname{Ho}(-, \mathbf{A})$ can be interpreted as computing equivariant cohomology and generalizations thereof:

Definition 3.2 (equivariant and relative cohomology) For $i: X \hookrightarrow \mathbf{X}$ a monomorphism in $\mathcal{C}_{0}$ it it is often useful to address $H^{\mathbf{X}}(X, \mathbf{A}):=\operatorname{Ho}_{\mathcal{C}_{0}}(\mathbf{X}, \mathbf{A})$ as equivariant cohomology on $X$, where the kind of equivariance is controlled by $i$. Conversely the kernel of $i^{*}$ for any $i: X \rightarrow \underline{X}$ is relative cohomology $H_{X}(\underline{X}, B)$ on $\mathbf{X}$ relative to $X$.

In terms of $\mathrm{Ho}_{\mathcal{C}}$ the familiar grading on cohomology is entirely implicit in the grading that the coefficient object $\mathbf{A}$ carries for cases that $\mathcal{V}$ may be interpreted as a category of graded or higher structures. To guarantee a consistent interpretation for which this is the case, we impose the additional condition that $\mathcal{V}$ be a category with interval object.

Definition 3.3 (category with interval object) A category with interval object is a closed monoidal category with tensor unit $I$ the terminal object - which we write $I \simeq \mathrm{pt}-$ and equipped with an internal co-category of the form $\mathrm{pt} \underset{\tau}{\underset{ }{\sigma}} \mathcal{I}$. We say $\mathcal{I}$ is the interval object.

In particular for $\mathcal{V}$ a category with interval object this means that

- there is a diagram of the form

with $c$ co-associative and co-unital in the obvious sense;
- for every object $B$ in a category $\mathcal{C}$ enriched and powered over $\mathcal{V}$ such that $[I, B] \simeq B$, there are canonical morphisms $B \xrightarrow{i}[\mathcal{I}, B] \xrightarrow{d_{0} \times d_{1}} B \times B$ and a composition morphism

which makes $[\mathcal{I}, B]$ a category internal to $\mathcal{C}_{0}$.
Definition 3.4 (directed and undirected objects) An object $B$ in a category with interval object is $\underline{\text { undirected }}$ if $B \xrightarrow{i}[\mathcal{I}, B]$ is a weak equivalence.

On undirected or groupoidal objects the computation of cohomology is usually easier, in particular if these arrange themselves into a category of fibrant objects in the sense of [7].

Definition 3.5 (compatible fibrant objects) A homotopical category with interval $\mathcal{I}$ has a compatible structure of a category of fibrant objects if it is equipped with the structure of a category of fibrant objects in the sense of [7] such that the weak equivalences of both structures coincide and such that for every object $B$ the object $[\mathcal{I}, B]$ with its canonical structure morphisms is a path object for $B$.

Since in a category of fibrant objects the morphisms $B \xrightarrow{i}[\mathcal{I}, B]$ are weak equivalences, the objects of such a category are undirected.

An important structure present in a category of fibrant objects is the factorization lemma.
Lemma 3.6 (factorization lemma [7]) In a category of fibrant objects for every morphism $\mathbf{X} \longrightarrow \mathbf{A}$ there is a diagram
 such that the acyclic fibration $p$ has a section $\sigma: \mathbf{X} \rightarrow \mathbf{Y}$.

It follows that for fixed $\mathbf{A}$ the functor $\operatorname{hom}(-, \mathbf{A}): \mathcal{C}_{0}^{\mathrm{op}} \rightarrow \mathcal{V}$ is homotopical (respects weak equivalences) and hence already coincides on objects with its right-derived functor if it sends acyclic fibrations to weak equivalences. The objects $\mathbf{A}$ for which this is true at least for acyclic fibrations $\pi: \mathbf{Y} \xrightarrow{\simeq} X$ over representables $X$ are called $\infty$-stacks. For each such $\pi$ the condition that hom $(-, \mathbf{A})$ be homotopical is that

$$
\operatorname{hom}(\pi, \mathbf{A}): \mathbf{A}(X) \simeq \operatorname{hom}(X, \mathbf{A}) \xrightarrow{\simeq} \operatorname{hom}(\mathbf{Y}, \mathbf{A})
$$

is a weak equivalence. This is the descent condition on $\mathbf{A}$ and $\operatorname{hom}(\mathbf{Y}, \mathbf{A})$ is the $\mathcal{V}$-object of descent data of A along $\pi$. Conversely, this means that the passage from $\mathcal{C}_{0}$ to $\mathrm{Ho}_{\mathcal{C}_{0}}$ is to be addressed as $\infty$-stackification.

Finally, sometimes we need to consider sub-categories of $\mathcal{C}_{0}$ which are pointed:
Definition 3.7 (pointed category) A category is pointed if it has has a 0 -object: an initial object isomorphic to a terminal object.

A $\mathcal{V}$-enriched homotipical category $\mathcal{C}$ with interval object is our general situation. A compatible structure of fibrant objects puts us in an undirected groupoidal context. Pointedness further puts us in the context of an abelian category. In the following let $\mathcal{P}_{0} \subset \mathcal{F}_{0} \subset \mathcal{C}_{0}$ be inclusions of full subcategories, with $\mathcal{F}_{0}$ a category of fibrant objects compatible with the homotopical structure induced $\mathcal{C}_{0}$ and $\mathcal{P}_{0}$ a pointed compatible category of fibrant objects.

Only for some applications, such as for discussion of the extension problem do we need to assume the full structure of a model category.

### 3.1 Pointed objects

In abelian homotopy theory one considers (for instance section 4 of [7]) the case that in the homotopical category exists an initial object isomorphic to the terminal one. This makes all objects uniquely pointed in the sense of the following definition and allows to define loop group objects of all objects.

To retain a nonabelian (directed) setup we generalize this to the case where there need not be an initial object isomorphic to the terminal object by instead considering objects equipped with a specified point. This leads to loop monoids and will allow us in particular to discuss not only higher principal bundles but also higher vector bundles.

Definition 3.8 (pointed object) The category of pointed objects in $\mathcal{C}_{0}$ is the under-category $\mathcal{C}_{0} \backslash \mathrm{pt}: ~ a$ pointed object is a morphism $\mathrm{pt} \xrightarrow{\mathrm{pt}_{F}} F$ and a morphism of pointed objects is a morphism $f: E \rightarrow F$ making the diagram

commute.
Lemma 3.9 The identity Id : pt $\rightarrow \mathrm{pt}$ is both the terminal as well as the initial object of $\mathcal{C}_{0} \backslash \mathrm{pt}$.
This says that $\mathcal{C}_{0} \backslash$ pt is pointed. In the following we consider operations on pointed objects but in all of $\mathcal{C}_{0}$, which itself need not be pointed.

Definition 3.10 (kernel and cokernel) The kernel $\operatorname{ker}(f)$ of a morphism $f: A \rightarrow B$ into a pointed object $B$ is the pullback

The cokernel coker $(f)$ of a morphism $f: B \rightarrow A$ is the pushout

The cokernel is naturally a pointed object $\mathrm{pt} \xrightarrow{\mathrm{pt}_{\text {coker }(f)}} \operatorname{coker}(f)$ as indicated, the kernel is naturally pointed if $A$ is a pointed object and $f$ a morphism of pointed objects, with the point $\mathrm{pt} \xrightarrow{\mathrm{pt}_{\operatorname{ker}(f)}} \operatorname{ker}(f)$ given by the
universal dashed morphism in

The kernel of a fibration of pointed objects is called its fiber.
If we have an ambient structure of a model category then by replacing limits and colimits in the above with their homotopy coherent versions, we obtain the homotopy kernel hoker $(f)$ and the homotopy cokernel hocoker ( $f$ ).

Definition 3.11 (monoid of loops) The monoid of loops $\Omega_{\mathrm{pt}} B$ of a pointed object $\mathrm{pt} \xrightarrow{\mathrm{pt}_{B}} B$ is the fiber of $[\mathcal{I}, B] \xrightarrow{d_{0} \times d_{1}} B \times B$ with $B \times B$ equipped with its canonical point $\mathrm{pt} \xrightarrow{\mathrm{pt}_{B} \times \mathrm{pt}_{B}} B \times B$, i.e. the pullback

equipped with the structure of a monoid induced from the structure of a co-category on $\mathcal{I}$.
Lemma 3.12 In the case that $\mathcal{V}$ is a category of fibrant objects with initial object isomorphic to the terminal one, the image of $\Omega_{\mathrm{pt}} B$ in the homotopy category is the loop group object considered in section 4 of [7].

### 3.2 Universal fiber bundles

Definition 3.13 (universal fiber bundles) For $\mathrm{pt}^{\mathrm{pt}_{B}} B$ a pointed object, the corresponding universal B-bundle is the morphism $p: \mathbf{E}_{\mathrm{pt}} B \longrightarrow B$ with $\mathbf{E}_{\mathrm{pt}} B$ the kernel of $[\mathcal{I}, F] \xrightarrow{d_{0}} F$ and $p$ the composite

Lemma 3.14 The fiber of the universal $B$-bundle $p: \mathbf{E}_{\mathrm{pt}} B \rightarrow B$ is the monoid of loops $\Omega_{\mathrm{pt}} B$.
Proof. Evidently

Notice that

Definition 3.15 There is a natural action $\rho: \mathbf{E}_{\mathrm{pt}} \times \Omega_{\mathrm{pt}} B \rightarrow \mathbf{E}_{\mathrm{pt}} B$ induced from the co-category structure on $\mathcal{I}$.

Lemma 3.16 This action is a morphism of bundles

Proposition 3.17 If $\mathcal{V}$ is compatibly a category of fibrant objects, then for every object $B$ the universal B-bundle

1. is an acyclic fibration over the point, $\mathbf{E}_{\mathrm{pt}} B \xrightarrow{\simeq} \mathrm{pt}$;
2. sits in a sequence $\Omega_{\mathrm{pt}} B \xrightarrow{i} \mathbf{E}_{\mathrm{pt}} B \xrightarrow{p} B$ with $p$ a fibration and $i$ the fiber $p$.

Proof. Recall from [7] that in a category of fibrant objects the maps $d_{0}, d_{1}:[\mathcal{I}, B] \xrightarrow{\simeq} B$ out of a path object are acyclic fibrations and that acyclic fibrations are preserved under pullback. Hence from

we find the acyclic fibration from $\mathbf{E}_{\mathrm{pt}} B$ to pt.
That $p$ is a fibration is a special case of the proof of the "factorization lemma" in [7]:
Using that pullbacks of fibrations are again fibrations, we obtain for all fibrant objects $C$ and $D$ that projections out of their product are fibrations

and for all morphisms $f: C \rightarrow D$ that the top left vertical morphisms in the double pullback square

is a fibration. Since composites of two fibrations are fibrations, it follows that $p$ in

is a fibration. Taking $f$ to be $\mathrm{pt} \xrightarrow{\mathrm{pt}_{B}} B$ this yields the desired statement for $p$.
Finally, that $i$ is the kernel of $p$ is lemma ??.

### 3.3 Cocycles and bundles

Now consider a subcategory $\mathcal{F}_{0} \subset \mathcal{C}_{0}$ of fibrant objects. By the central theorem in [7] morphisms in the homotopy category $\operatorname{Ho}_{\mathcal{F}_{0}}$ are represented already by single spans whose left leg is an acyclic fibration.

Definition 3.18 (anamorphisms) An anamorphism or cocycle on $X$ with values in $A$ is a span $\begin{array}{ll}\hat{X} \longrightarrow \\ & \downarrow \\ & \end{array}$
Lemma 3.19 Anamorphisms have a consistent composition induced by pullback

which is associative and unital up to isomorphism of spans.
Definition 3.20 (bundles obtained from cocycles) Given a cocycle $X \underset{ }{\simeq} \hat{X} \xrightarrow{g} B$ into a pointed object $\mathrm{pt} \xrightarrow{\mathrm{pt}_{B}} B$ the corresponding $B$-bundle $p: g^{*} \mathbf{E}_{\mathrm{pt}} B \longrightarrow X$ is the pullback

This bundle inherits an action $\rho:\left(g^{*} \mathbf{E}_{\mathrm{pt}} B\right) \times \Omega_{\mathrm{pt}} B \rightarrow g^{*} \mathbf{E}_{\mathrm{pt}} B$ of the monoid of loops from the commutativity of

Lemma 3.21 This induced action is still a morphism of bundles

Definition 3.22 (fiber bundle) We say the morphism $P \longrightarrow X$ equipped with an action of $\Omega_{\mathrm{pt}} B$ is a $B$-fiber bundle if there is a cocycle $X \longleftarrow \simeq \sim \hat{X} \xrightarrow{g} B$ and a weak equivalence $g^{*} \mathbf{E}_{\mathrm{pt}} B \xrightarrow{\simeq} P$ respecting the $\Omega_{\mathrm{pt}} B$-action on both sides.

Proposition 3.23 (fiber bundle trivializes over itself) In the category $\mathcal{F}_{0}$ of fibrant objects, every fiber bundle $P \rightarrow X$ becomes trivializable when pulled back along itself.

Proof. For $X \longleftarrow \sim \simeq \hat{X} \longrightarrow B$ a cocycle characterizing the bundle $P \rightarrow X$ we obtain the pullback diagram

The cocycle $g$ pulled back to $P$ is represented by the morphism from $g^{*} \mathbf{E}_{\mathrm{pt}} B$ to the $B$ at the bottom. The right part of the diagram says that this is homotopic to a map factoring through the point.

Definition 3.24 (associated bundle) Let $g^{*} \mathbf{E}_{\mathrm{pt}} B \rightarrow X$ be a $B$-bundle as above and let $\rho: B \rightarrow F$ be a morphism in $\mathcal{C}_{0}$ to a pointed object $\mathrm{pt} \xrightarrow{\mathrm{pt}_{F}} F$ not necessarily fibrant. Then we call $\rho$ a representation of $B$ on $F$ and call the pullback

the associated bundle, associated by $\rho$ to $P$.
So in particular $\rho^{*} \mathbf{E}_{\mathrm{pt}} F$ is the $F$ bundle $\rho$-associated to the univeral $B$-bundle.

### 3.4 Sections and homotopies

One way to think of a section of an $\omega$-bundle is as a morphism from a certain trivial $\omega$-bundle into it. The following formalizes this and then provides reformulations of this notion which are useful later on in section 5.

Definition 3.25 (section) A section $\sigma$ of an $F$-cocycle $\hat{X} \xrightarrow{\nabla} F$ is a directed homotopy from the trivial $F$-cocycle with fiber $\mathrm{pt}_{F}$ into $\nabla$.

Proposition 3.26 If the $F$-cocycle $\nabla$ is $\rho$-associated to a $B$-cocycle $\hat{X} \xrightarrow{g} B$ then sections of $\nabla$ are equivalently lifts of $g$ through $\rho^{*} \mathbf{E}_{\mathrm{pt}} F \longrightarrow \mathbf{B} G$

$$
\Gamma(\nabla) \simeq\left\{\right\}
$$

Proof. First rewrite

using the characterization of right (directed) homotopies by the (directed) path object $[\mathcal{I}, F]$. Using the universal property of $\mathbf{E}_{\mathrm{pt}} F$ as a pullback this yields

A third way to think about sections comes from observing that since a directed homotopy between two cocycles
 it can itself be regarded as an $[\mathcal{I}, F]$-cocycle.

Definition 3.27 (universal $F^{\mathcal{I}}$-bundle) The object $[\mathcal{I}, F]$ is naturally equipped with the point $\mathrm{pt}_{[\mathcal{I}, F]} d e$ fined by

We write $\mathbf{E}_{\mathrm{pt}}([\mathcal{I}, F]) \longrightarrow[\mathcal{I}, F]$ for the corresponding universal $[\mathcal{I}, F]$-bundle according to definition 3.13.
Notice the commutativity of the diagram

for $i=0$ and $i=1$. The right square commutes by the functoriality of $[\mathcal{I},-]$, the left square and the bottom triangle by definition 3.27 of the universal $[\mathcal{I}, F]$-bundle.

Definition 3.28 Let $\mathbf{E}_{\mathrm{pt}} F \stackrel{\mathbf{E}_{\mathrm{pt}} d_{0}}{-} \mathbf{E}_{\mathrm{pt}}([\mathcal{I}, F]) \stackrel{\mathbf{E}_{\mathrm{pt}} d_{1}}{-}>\mathbf{E}_{\mathrm{pt}} F$ be the universal morphisms induced from the commutativity of the outermost rectangle of the above diagram in view of the universal property of $\mathbf{E} F$ as a pullback.

Proposition 3.29 The morphism $\mathbf{E} d_{0} \times \mathbf{E} d_{1}$ covers the morphism $[\mathcal{I}, F] \xrightarrow{d_{0} \times d_{1}} F \times F$ of base spaces:

Proof. By inspection of the above commuting diagram.
This is sometimes called a concordance of bundles.
In total this yields for every homotopy of $F$-cocycles a span of the corresponding bundles.
Definition 3.30 (associated span of bundles) For $\hat{Q}^{\iota} \bigwedge_{\iota^{\prime}}^{\hat{X}}{ }_{\hat{Y}}^{\hat{\prime}}{ }^{\nabla_{1}}$ a directed homotopy of $F$-cocycles, we
say that the rear of the joint pullback diagram

is the associated span of $\omega$-bundles.
From definition 3.11 notice the following observation:

Lemma 3.31 In the case that the homotopy in question is a section
 ${ }_{\mathrm{pt}_{F}}{ }_{F}{ }_{\sigma}$ associated span of bundles is of the form $\Omega_{\mathrm{pt}} F$ with $\Omega_{\mathrm{pt}} F$ the monoid of loops from definition 3.11.

Remark on groupoidification. In the cased that $\mathcal{F}_{0}$ is a category of $\infty$-groupoids, this realizes a section of an associated bundle as an $\infty$-groupoid over the total space $\infty$-groupoid of the associated $\infty$-bundle, and equipped with a map to to the ground $\infty$-monoid. Since this is the description of vectors in the context of groupoidification [1, 2] it motivates the following definition.

Definition 3.32 (generalized sections of associated $\omega$-bundles) Given an $F$-bundle $V:=\nabla^{*} \mathbf{E}_{\mathrm{pt}} F$, its generalized sections are spans $|\Psi\rangle:=\Omega_{\mathrm{pt}} F^{\Psi} \searrow_{V}$ and its generalized co-sections are spans $\langle\Psi|:=$ $\swarrow^{\Psi} \searrow_{\Omega_{\mathrm{pt}}} F$. We write $\mathcal{H}(V)$ for the collection of all generalized sections of $V$.

### 3.5 Extension and lifting problem

### 3.5.1 Extension

Assume for the following that on $\mathcal{C}_{0}$ we have a full structure of a model category.

Consider extensions $\underline{g}$ of morphisms $g$ along morphisms $i$

Definition 3.33 (equivariant structure and flat connection) An extension through a morphism $i$ : $A C X$ which is an isomorphism from the points of $A$ to the points of $X$

$$
[\mathrm{pt}, A] \stackrel{i_{*}}{\sim}[\mathrm{pt}, X]
$$

is called an i-equivariant structure or an i-flat connection.
Theorem 3.34 (long exact sequence for extensions) For every object $B$ for which there is a diagram

and for every extension $\iota: X \rightarrow \underline{X}$ there is a morphism $\delta: H(X, B) \rightarrow H_{X}(\underline{X}, \operatorname{hocoker}(i))$ whose kernel is the image of $\iota^{*}$. If furthermore $i$ is the homotopy kernel of $p$ then then image of $\delta$ is the kernel of $H_{X}(\underline{X}, \operatorname{hocoker}(i)) \rightarrow H(X, \operatorname{hocoker}(i))$ so that we get a semi-long exact sequence in cohomology

$$
H_{X}(\underline{X}, B) \longrightarrow H(\underline{X}, B) \xrightarrow{i^{*}} H(X, B) \xrightarrow{\delta} H_{X}(\underline{X}, \operatorname{hocoker}(i)) \longrightarrow H(\underline{X}, \operatorname{hocoker}(i)) \longrightarrow \cdots
$$

Proof. (the idea)
The connecting homomorphism $\delta$ is obtained by first constructing a diagram

and then setting $\delta g:=p \circ F$. Here the existence of the cofibration $\hat{\imath}$ follows from the general factorization property in a model category, while $F$ is constructed as the dashed morphism in

which exists by the lifting property of cofibrations. By the property of a homotopy colimit $\delta g$ is precisely the obstruction for the dashed lift to exists. That every cocycle in $H(\underline{X}, \operatorname{coker}(i))$ which trivializes under $i^{*}$ arises this way follows by using that $i=\operatorname{hoker}(p) \ldots$

Definition 3.35 (curvature and characteristic classes) Here $F$ is the curvature, $\delta g$ the characteristic classes of $g$ for the extension along $i$.

### 3.5.2 Lifting

...

### 3.5.3 Local semi-trivializations

Proposition 3.23 states that every $B$-bundle trivializes over its own total space. If $\hat{B}$ is part of an exact sequence $A \xrightarrow{i} \hat{B} \xrightarrow{p} B$, with $i$ the homotopy kernel of $p$, then there is a relative version of this statement, which states that a $\hat{B}$ bundle becomes equivalent to an $A$-bundle with a certain $\hat{B}$-equivariance on the total space of the underlying $B$-bundle.

Definition 3.36 (relative equivariance) For $\pi: P \rightarrow X$ a $B$-bundle we say a cocycle $P \longrightarrow \mid \rightarrow A$ on its total space is relatively equivariant with respect to the above sequence if

- there exists $\hat{B}$-cocycle $\underline{g}$ on $X$
- and a homotppy $\pi^{*} \underline{g} \Rightarrow p^{*} g$
- and such that $P$ is classified by $p^{*} g$

Proposition 3.37 (local semi-trivialization) $\hat{B}$-cohomology on $X$ is in bijection with relatively equivariant $A$-cohomology on the underlying B-bundles.

Proof. Consider

## 4 Examples and Applications

### 4.1 Homotopical contexts

- $\mathcal{V}=$ SimplicialSets: the theory of $\operatorname{Ho}_{\left[S^{\circ \mathrm{op}}, \mathcal{V}\right]}$ developed in great detail in series of articles by Toën [?].

### 4.2 Closed monoidal homotopical categories

- Cat with standard tensor and folk model structure
- 2Cat with Gray tensor and Lack model structure
- $\omega$ Cat with Crans-Gray tensor and folk model structure (need to confirm some axioms of closed monoidal homotopical).
- $\omega$ Groupoids with Brown-Golasiski tensor and model structure (need to confirm some axioms of closed monoidal homotopical).

### 4.3 Pointed objects

- one-object $\omega$-groupoids pt! $\xrightarrow{\exists} \mathrm{B} G$
- category of vector spaces, point maps to ground field pt $\xrightarrow{\mathrm{pt} \mapsto k}$ Vect $_{k}$
- similarly for higher vector spaces,

### 4.4 Monoid of loops

1. for pt $\xrightarrow{\rightrightarrows!} \mathbf{B} G$ we have $\Omega \mathbf{B} G=G$.
2. for $\mathrm{pt} \xrightarrow{\mathrm{pt} \leftrightarrow k}$ Vect $_{k}$ we have $\Omega_{\mathrm{pt}}$ Vect $=k$,
3. for $\mathrm{pt} \longrightarrow 2$ Vect $_{k}$ we have $\Omega_{\mathrm{pt}} 2$ Vect $=$ Vect $_{k}$, etc.

### 4.5 Universal bundles

1. for $B=\mathbf{B} G$ and $G$ a 1-group the universal $B$-bundle is $\mathbf{E} G:=G / / G$ is the action groupoid of $G$ acting on itself and the sequence $G \longrightarrow \mathbf{E} G \longrightarrow \mathbf{B} G$ maps under nerve and topological realization to the universal $G$-bundle in its incarnation in topological spaces. This is discussed in [25] as a preparation for the following example.
2. for $B=\mathbf{B} G$ and $G$ a 2-group or bi-group [4] shows that $\mathbf{E} G$ is the action bigroupoid of $G$ acting on itself. we show that $\mathbf{E} G$ is the universal 2-bundle (sketched in [25]).

### 4.6 Bundles

- $\rho: \mathbf{B} G \rightarrow$ Vect a representation, then $\rho^{*} \mathbf{E}_{\mathrm{pt}}$ Vect is the action groupoid ( $\rho$-associated vector bundle of $\mathrm{E} G$ )
- pullback along $G_{1}$-cocycle $g$ weakly equivalent to $G$-principal bundle;
- pullback along $G_{2}$-cocycle $g$ weakly equivalent to $G_{2}$-principal 2-bundle (Bartels, Baković, Wockel);
- combined pullback $g^{*} \circ \rho^{*}$ weakly equivalent to associated bundle
etc. pp.

### 4.7 Lifting problems

### 4.8 Extension problem

- ; $X \hookrightarrow X / / G$ : ordinary equivariance under $G$-action; connection homomorphism computes obstruction to having equivariant structure;
- $X \hookrightarrow \Pi(X)$ : flat connection, connection homomorphism computes curvature (characteristic forms);

### 4.9 Equivariance on semi-total spaces

- for $\mathbf{B} U(1) \rightarrow \operatorname{AUT}(U(1)) \rightarrow \mathbb{Z}_{2}$ this yields Jandl gerbes [34]
- for $\mathbf{B} U(1) \rightarrow \operatorname{String}(G) \rightarrow G$ this yields String bundle gerbes on the total space of a $G$-bundle
- etc.

## 5 Quantization of nonabelian cocycles to $\sigma$-models

We want to think of a $\rho$-associated $F$-cocycle $\hat{X} \xrightarrow{\nabla} F$ and the corresponding $F$-bundle $\nabla^{*} \mathbf{E}_{\mathrm{pt}} F \longrightarrow X$ as a background field (a generalization of an electromagnetic field) on $X$ to which a higher dimensional fundamental brane - such as a particle, a string or a membrane - propagating on $X$ may couple.

We now propose a formalization in the context of homotopical cohomology of what it means to quantize such a background field to obtain the corresponding $\sigma$-model quantum field theory as a functorial QFT (as described in [31] and references given there). Our constructions are motivated by and supposed to implement and generalize the considerations of $[15,42]$ and make contact with [24].

We define a notion of parameter space or worldvolume category and a notion of background field over a target space coming from an $\omega$-bundle. This pair of data we call a $\sigma$-model, We show how this data induces a functor from the parameter space category to spans in $\omega$-groupoids. Using methods from groupoidification $[1,2]$ we show that these spans represent linear maps which deserve to be addressed as propagation in the quantum field theory induced by the $\sigma$-model.

## $5.1 \quad \sigma$-Models

In the following $B:=\mathbf{B} G$ denotes an object of $\mathcal{F}_{0}$ which we think of as modelling a one object $\infty$-groupoid the automorphisms of whose single object form the $\infty$-group $G$. At the moment this is just notation meant to be suggestive.

Definition 5.1 (background structure) A background structure for a $\sigma$-model is

- an $\omega$-groupoid $X$ called target space;
- an $\omega$-group $G$, called the gauge group;
- a representation
 called the matter content;
- an F-cocycle $\underset{\longrightarrow}{\hat{X}} \stackrel{\nabla}{\downarrow}$ $\rho$-associated to a G-principal cocycle on $X, \nabla: \hat{X} \xrightarrow{g} \mathbf{B} G \xrightarrow{\rho} F$, called the background field.

For brevity we shall indicate a background structure just as ( $\hat{X} \xrightarrow{\nabla} F$ ), leaving the choice of representation and the target space $X$ weakly equivalent to the hypercover $\hat{X}$ implicit.

Definition 5.2 (parameter space category) A parameter space $\omega$-category Cob is a sub $\omega$-category of Cospans( $\omega$ Groupoids).

Definition 5.3 ( $\sigma$-model) A $\underline{\sigma-m o d e l}$ is a pair consisting of a parameter space category and a background structure for a $\sigma$-model.

Definition 5.4 Given a $\sigma$-model with background structure $\nabla: \hat{X} \xrightarrow{\nabla} F$ and with parameter space Cob for every object $\Sigma \in \mathrm{Cob}$ we say that

- $C(\Sigma):=[\Sigma, \hat{X}]$ is the space of fields over $\Sigma ;$
- The $[\Sigma, F]$-cocycle $[\Sigma, \nabla]:[\Sigma, \hat{X}] \rightarrow[\Sigma, F]$ on the space of fields over $\Sigma$ is the action functional over $\Sigma$.

Remark. One can identify $[\Sigma, \nabla]$ with the transgression of the cocycle $g$ to the mapping space $[\Sigma, X]$. Examples showing that this canonical operation indeed reproduces the ordinary notion of transgression of cocycles are in $[35,36]$ and in our section 6 .

In section 5.3 we construct for every $\sigma$-model its corresponding quantum field theory. This involves the notion of bibranes discussed in section 5.2.

### 5.2 Branes and bibranes

From the second part of definition 3.25 one sees that spaces spaces of sections of $\omega$-bundles are given by certain morphisms between background fields pulled back to spans/correspondences of target spaces. From the diagrammtics this has an immediate generalization, which leads to the notion of branes and bibranes.

Definition 5.5 (branes and bibranes) A brane for a background structure ( $\hat{X} \xrightarrow{\nabla} F$ ) is a morphism
$\iota: \hat{Q} \rightarrow \hat{X}$ equipped with a section of the background field pulled back to $\hat{Q}$, i.e. a transformation

More generally, given two background structures $(\hat{X} \xrightarrow{\nabla} F)$ and ( $\left.\hat{X}^{\prime} \xrightarrow{\nabla^{\prime}} F\right)$, a bibrane between them

Bibranes may be composed -"fused" - along common background structures $(\hat{X} \xrightarrow{\nabla} F)$ : the composite or fusion of a bibrane $V_{1}$ on $\hat{Q}$ with a bibrane $V_{2}$ on $\hat{Q}^{\prime}$ is the bibrane $V_{1} \cdot V_{2}$ given by the diagram

Proposition 5.6 (composition of associated spans from fusion of bibranes) The associated span of $\omega$-groupoids corresponding, according to definition 3.30, to the fusion of two bibranes is the composition of the spans associated with each bibrane:

Proof. By commutativity of pullbacks.

Remark on groupoidification. Comparing with the remark above definition 3.32 we find that fusion of bibranes corresponds to composition of groupoidified linear maps.

If $\hat{Q}$ carries further structure, the fused bibrane on $\hat{Q} \times_{\hat{Y}} \hat{Q}$ may be pushed down again to $\hat{Q}$.

Definition 5.7 Let $B$ be a category enriched in the bicategory $\mathcal{V}:=\operatorname{Spans}(\omega$ Categories) of spans in $\omega$ Categories and let $F$ be an $\omega$-category. Then the category of bibranes relative to $B$ and $F$ is given by:

- objects are background structures $\hat{X} \xrightarrow{\nabla} F$ for $\hat{X}$ an object of $B$;
- morphisms are bibranes on morphisms of B;
- composition of morphisms is given by bibrane fusion followed by push-forward along the composition map in B.

A simple special case is a category $\hat{Q} \xrightarrow{\stackrel{s}{\longrightarrow}} \hat{X}$ internal to $\omega$-groupoids, equivalently a monad in the bicategory of spans internal to $\omega$ Groupoids, with composition operation the morphism of spans

Definition 5.8 (monoidal structure on bibranes) Given an internal category as above, and given a $\hat{Q}$
background structure $\nabla: \hat{X} \rightarrow F$, the composite of two bibranes

forming their composite bibrane on on $\hat{Q} \times_{t, s} \hat{Q}$ and then pushing that forward along comp:

$$
V \star W:=\int_{\text {comp }}\left(s^{*} V\right) \cdot\left(t^{*} W\right) .
$$

Here for finite cases, which we concentrate on, push-forward is taken to be the right adjoint to the pullback in a proper context.

Remarks. Notice that branes are special cases of bibranes and that bibrane composition restricts to an action of bibranes on branes. Also recall that the sections of a cocycle on $X$ are the same as the branes of this cocycle for $\iota=\operatorname{Id}_{X}$.

The idea of bibranes was first formulated in [17] in the language of modules for bundle gerbes. We show in section 6.1.4 how this is reproduced within the present formulation. In its smooth $L_{\infty}$-algebraic version the idea also appears in [28].

### 5.3 Quantum propagation

Every $\sigma$-model with parameter space Cob and background structure $\hat{X} \xrightarrow{\nabla} F$ induces a functor

$$
\exp \left(\int \nabla\right): \operatorname{Cob} \rightarrow \operatorname{Spans}(\omega \text { Groupoids })
$$

which sends

$$
\exp \left(\int \nabla\right): \Sigma_{\Sigma_{\mathrm{in}}}^{\stackrel{\iota}{\Sigma_{\text {out }}}} \stackrel{[\Sigma, \nabla]^{*} \mathbf{E}_{\mathrm{pt}}[\Sigma, F]}{\left[\Sigma_{\mathrm{in}}, \nabla\right]^{*} \mathbf{E}_{\mathrm{pt}}\left[\Sigma_{\mathrm{in}}, \nabla\right]}
$$

a morphism $\Sigma: \Sigma_{\text {in }} \rightarrow \Sigma_{\text {out }}$ in Cob to the span of $\omega$-bundles associated to, definition 3.30, the bibrane on the span

which is induced by transgression of the background field:

A state of the $\sigma$-model over $\Sigma$ is a generalized section, definition 3.32 of $\left[\Sigma_{a}, \nabla\right]$ in $\mathcal{H}_{a}:=\mathcal{H}\left(\left[\Sigma_{a}, \nabla\right]\right)$ and the propagation of along a morphism $\Sigma$ is the map

$$
\int_{\operatorname{hom}(\Sigma, X)} \exp \left(\int \nabla\right): \mathcal{H}_{\Sigma_{\text {in }}} \longrightarrow \mathcal{H}_{\Sigma_{\text {out }}}
$$

induced by pull-push through the span $\exp \left(\int \nabla\right)(\Sigma)$.
An example is spelled out in section 6.1.6.

## 6 Examples and applications

We start with some simple applications to illustrate the formalism and then exhibit some useful constructions in the context of finite group quantum field theory.

### 6.1 General examples

### 6.1.1 Ordinary vector bundles

Let $G$ be an orinary group, hence a 1-group, and denote by $F:=$ Vect the 1-category of vector spaces over some chosen ground field $k$. A linear representation $\rho$ of $G$ on a vector space $V$ is indeed the same thing as a functor $\rho: \mathbf{B} G \rightarrow$ Vect which sends the single object of $\mathbf{B} G$ to $V$.

The canonical choice of point $\mathrm{pt}_{F}: \mathrm{pt} \rightarrow$ Vect is the ground field $k$, regarded as the canonical 1dimensional vector space over itself. Using this we find

- from definition ?? that the ground $\omega$-monoid in this case is just the ground field itself, $K=k$,
- from definition ?? that the universal Vect-bundle is $\mathbf{E}_{\mathrm{pt}}$ Vect $=$ Vect ${ }_{*}$, the category of pointed vector spaces with Vect ${ }_{*} \longrightarrow$ Vect the canonical forgetful functor;
- from definition ?? that the $\rho$-associated vector bundle to the universal $G$-bundle is $V / / G \longrightarrow \mathbf{B} G$, where $V / / G:=\left(V \times G \xrightarrow[\rho]{\stackrel{p_{1}}{\longrightarrow}} V\right)$ is the action groupoid of $G$ acting on $V$, the weak quotient of $V$ by $G ;$
- From definition 3.25 that for $g: X \longrightarrow \xrightarrow{g} \rightarrow \mathbf{B} G$ a cocycle describing a $G$-principal bundle and for $V$ the corresponding $\rho$-associated vector bundle according to definition ??, that sections $\sigma \in \Gamma(V)$ are precisely sections of $V$ in the ordinary sense.

### 6.1.2 Group algebras and category algebras from bibrane monoids

In its simplest version the notion of monoidal bibranes from section 5.2 reproduces the notion of category algebra $k[C]$ of a category $C$, hence also that of a group algebra $k[G]$ of a group $G$. Recall that the category algebra $k[C]$ of $C$ is defined to have as underlying vector space the span of $C_{1}, k[C]=\operatorname{span}_{k}\left(C_{1}\right)$, where the product is given on generating elements $f, g \in C_{1}$ by

$$
f \cdot g=\left\{\begin{array}{cl}
g \circ f & \text { if the composite exists } \\
0 & \text { otherwise }
\end{array}\right.
$$

To reproduce this as a monoid of bibranes in the sense of section 5.2, take the category of fibers in the sense of section ?? to be $F=$ Vect as in section 6.1.1. Consider on the space (set) of objects, $C_{0}$, the trivial line bundle given as an $F$-cocycle by $i: C_{0} \longrightarrow \mathrm{pt} \xrightarrow{\mathrm{pt}_{k}}$ Vect. An element in the monoid of bibranes for this trivial line bundle on the span given by the source and target map

 a function $V: C_{1} \rightarrow k$ from the space (set) of morphisms to the ground field and every such function gives such a transformation. This identifies the $C$-bibranes with functions on $C_{1}$.

Given two such bibranes $V, W$, their product as bibranes is, according to definition 5.8 , the push-forward along the composition map on $C$ of the function on the space (set) of composable morphisms

$$
\begin{gathered}
C_{1} \times_{t, s} C_{1} \rightarrow k \\
(\xrightarrow{f} \xrightarrow{g}) \mapsto V(f) \cdot W(g) .
\end{gathered}
$$

This push-forward is indeed the product operation on the category algebra.

### 6.1.3 Monoidal categories of graded vector spaces from bibrane monoids

The straightforward categorification of the discussion of group algebras in section 6.1.2 leads to bibrane monoids equivalent to monoidal categories of graded vector spaces.

Let now $F:=2$ Vect be a model for the 2-category of 2-vector spaces. For our purposes and for simplicity, it is sufficient to take $F:=\mathbf{B V e c t} \hookrightarrow$ 2Vect, the 2-category with a single object, vector spaces as morphims with composition being the tensor product, and linear maps as 2-morphisms. This can be regarded as the full sub-2-category of 2Vect on 1-dimensional 2-vector spaces. And we can assume BVect to be strictified.

Notice from definition ?? that the ground $\omega$-monoid in this case is the monoidal category $K=$ Vect.
Then bibranes over $G$ for the trivial 2 -vector bundle on the point, i.e. transformations of the form

canonically form the category Vect ${ }^{G}$ of $G$-graded vector spaces. The fusion of such bibranes

BVect
reproduces the standard monoidal structure on $\operatorname{Vect}^{G}$.

### 6.1.4 Twisted vector bundles

The ordinary notion of a brane in string theory is: for an abelian gerbe $\mathcal{G}$ on target space $X$ a map $\iota: Q \rightarrow X$ and a $\mathrm{PU}(n)$-principal bundle on $Q$ whose lifting gerbe for a lift to a $U(n)$-bundle is the pulled back gerbe $\iota^{*} \mathcal{G}$. Equivalently: a twisted $U(n)$-bundle on $Q$ whose twist is $\iota^{*} \mathcal{G}$. Equivalently: a gerbe module for $\iota^{*} \mathcal{G}$.

We show how this is reproduced as a special case of the general notion of branes from definition 5.5 , see also [37].

The bundle gerbe on $X$ is given by a cocycle $g: X \longrightarrow \mathbf{B B} U(1)$. The coefficient group has a canonical representation $\rho: \mathbf{B}^{2} U(1) \rightarrow F:=\mathbf{B V e c t} \hookrightarrow 2$ Vect on 2 -vector spaces (as in section 6.1.3) given by

See also [37, 31].

By inspection one indeed finds that branes in the sense of diagrams

identified with twisted vector bundles on $Q$ with twist given by the $\iota^{*} g$ : the naturality condition satisfied by the components of $V$ is

for all $y \in Y \times_{X} Y \times_{X} Y \times_{X} Y$ in the triple fiber product of a local-sections admitting map $\pi: Y \rightarrow X$ whose simplicial nerve $Y^{\bullet}$, regarded as an $\omega$-category, provides the cover for the $\omega$-anafunctor $X \longleftrightarrow \simeq \sim Y^{\bullet} \xrightarrow{g} \mathbf{B}^{2} U(1)$ representing the gerbe. See [37] for details. $E \rightarrow Y$ is the vector bundle on the cover encoded by the transformation $V$. The above naturality diagram says that its transition function $g_{\mathrm{tw}}$ satisfies the usual cocycle
condition for a bundle only up to the twist given by the gerbe $g$ : if $Y \rightarrow X$ is a cover by open subsets $Y=\sqcup_{i} U_{i}$, then the above diagram is equivalent to the familiar equation

$$
\left(g_{\mathrm{tw}}\right)_{i j}\left(g_{\mathrm{tw}}\right)_{j k}=\left(g_{\mathrm{tw}}\right)_{i k} \cdot g_{i j k}
$$

In this functorial cocyclic form twisted bundles on branes were described in [30, 37].

### 6.1.5 2-Hilbert spaces

Let $B$ be the category internal to spans in $\omega$-categories given by all product spans in Sets with composition morphisms the canonical morphisms. Let $F=\mathbf{B V e c t}$ as before. Then the 2-category of $(B, F)$-bibranes is the 2 -category of 2 -Hilbert spaces as in [6].

### 6.1.6 The path integral

We unwrap the notion of propagation in a $\sigma$-model form section 5.3 for the case that the background field is an ordinary vector bundle (with connection), i.e. for the case $F=$ Vect. This can be regarded in terms of the quantization of the charged 1-particle as well as, after transgression, as the top-dimensional propagation in higher dimensional theories. We shall re-encounter this example in the discussion of Dijkgraaf-Witten theory in section 6.2 .

Let for the present example the parameter space Cob consist just of a single edge

$$
\operatorname{Cob}=\left\{\begin{array}{c}
\stackrel{\Sigma}{\Sigma}:=\{a \rightarrow b\} \\
\Sigma_{\text {in }}:=\{a\} \\
\Sigma_{\text {in }}:=\{b\}
\end{array}\right\}
$$

Recall from section 6.1.1 that for $F=$ Vect and $\rho: \mathbf{B} G \rightarrow$ Vect a linear representation, we have $\rho^{*} \mathbf{E}_{\mathrm{pt}} F=V / / G$ is the action groupoid of $G$ acting on the representation space $V$.

Write $\nabla:=\rho \circ g$ for the background field. It follows that the $\omega$-bundle over $X$ is given by the groupoid $\nabla^{*} \mathbf{E}_{\mathrm{pt}} F$ with morphisms

$$
\left(\nabla^{*} \mathbf{E}_{\mathrm{pt}} F\right)_{1}=\left\{\left(x_{1}, v_{1}\right) \xrightarrow{\gamma}\left(x_{2}, v_{2}\right) \mid(x \xrightarrow{\gamma} y) \in X, v_{1}, v_{2} \in V, v_{2}=\rho(g(\gamma))\right\}
$$

with the obvious composition operation.
So a state in $\mathcal{H}_{\Sigma_{a}}$, a groupoid $v: \Psi \rightarrow \nabla^{*} V / / G$ over $\nabla^{*} V / / G$, is over each point $x \in X$ a groupoid over $V$. By the yoga of groupoid cardinality $[1,2]$ we can hence identify a state $v: \Psi \rightarrow \nabla^{*} V / / G$ with a $V$-valued function on $\operatorname{Obj}(X)$.

The objects of the transgressed background bundle $\left(\nabla^{\Sigma}\right)^{*} \mathbf{E}_{\mathrm{pt}}\left(F^{\Sigma}\right)$ are the morphisms of $\nabla^{*} \mathbf{E}_{\mathrm{pt}} F$.
The pull-push propagation map

$$
\int_{\operatorname{hom}(\Sigma, X)} \exp \left(\int \nabla\right): \mathcal{H}_{a} \rightarrow \mathcal{H}_{b}
$$

reproduces the path integral in this setup as described in [32].

### 6.2 Dijkgraaf-Witten model: target space $\mathbf{B} G_{1}$

Dijkgraaf-Witten theory [16] is the $\sigma$-model which in our terms is specified by the data

- target space $X=\mathbf{B} G$, the one-object groupoid corresponding to an ordinary 1-group $G$;
- background field $\alpha: \mathbf{B} G \rightarrow \mathbf{B}^{3} U(1)$, a group 3-cocycle on $G$.

### 6.2.1 The 3-cocycle

Indeed, we can understand group cocycles precisely as $\omega$-anafunctors $\mathbf{B} G \longleftarrow \simeq \simeq \xrightarrow{\alpha} \mathbf{B}^{n} U(1)$. This is described in [8]. Here it is convenient to take $Y$ to be essentially the free $\omega$-category on the nerve of $\mathbf{B} G$, i.e. $Y:=F(N(\mathbf{B} G))$, but with a few formal inverses thrown in to ensure that we have an acyclic fibration to $\mathbf{B} G$ :
the 1-morphisms of $Y$ are given by finite sequences of elements of $G$, its 2-morphisms are freely generated as pasting diagrams from 2-morphisms of the form $\{$ e inverses. Its 3-morphisms are freely generated as pasting diagrams from 3-morphisms of the form

together with their formal inverses. Its 4-morphisms are freely generated from pasting diagrams of 4morphisms of the form

together with their formal inverses.

The $\omega$-functor $\alpha: Y \rightarrow \mathbf{B}^{3} U(1)$ has to send the generating 3-morphisms $(g, h, k)$ to a 3-morphism in $\mathbf{B}^{3} U(1)$, which is an element $\alpha(g, h, k) \in U(1)$. In addition, it has to map the generating 4 -morphisms between pasting diagrams of these 3 -morphisms to 4 -morphisms in $\mathbf{B}^{3} U(1)$. Since there are only identity 4-morphisms in $\mathbf{B}^{3} U(1)$ and since composition of 3-morphisms in $\mathbf{B}^{3} U(1)$ is just the product in $U(1)$, this says that $\alpha$ has to satisfy the equations

$$
\forall g, h, k, l \in G: \alpha(g, h, k) \alpha(g, k h, l) \alpha(h, k, l)=\alpha(h g, k, l) \alpha(g, h, l k)
$$

in $U(1)$. This identifies the $\omega$-functor $\alpha$ with a group 3-cocycle on $G$. Conversely, every group 3-cocycle gives rise to such an $\omega$-functor and one can check that coboundaries of group cocycles correspond precisely to transformations between these $\omega$-functors. Notice that $\alpha$ uniquely extends to the additional formal inverses of cells in $Y$ which ensure that $Y \xrightarrow{\simeq} \mathbf{B} G$ is indeed an acyclic fibration. For instance the 3-cell

has to go to $\alpha(g, h, k)^{-1}$.

### 6.2.2 Chern-Simons theory

In this article we do not want to get into details of the discussion of $\omega$-categories internal to smooth spaces, but in light of the previous section 6.2 it should be noted that in terms of nonabelian cocycles the appearance of Chern-Simons theory is formally essentially the same as that of Dijkgraaf-Witten theory:
if we take $B G$ to be a smooth model of the classifying space of $G$-principal bundles, then a smooth cocycle $B G \longrightarrow \mathbf{B}^{3} U(1)$, i.e. an $\omega$-anafunctor internal to (suitably generalized) smooth spaces is precisely the cocycle for a 2 -gerbe, i.e. a line 3 -bundle. In nonabelian cohomology, the difference between group cocycles and higher bundles is no longer a conceptual difference, but just a matter of choice of target "space" $\omega$ groupoid.

### 6.2.3 Transgression of DW theory to loop space

Proposition 6.1 The background field $\alpha$ of Dijkgraaf-Witten theory transgressed according to definition 5.4 to the mapping space of parameter space $\Sigma:=\mathbf{B} \mathbb{Z}-a$ combinatorial model of the circle -

$$
\tau_{\mathbf{B} \mathbb{Z}} \alpha:=\operatorname{hom}(\mathbf{B} \mathbb{Z}, \alpha)_{1}: \Lambda G \rightarrow \mathbf{B}^{2} U(1)
$$

is the groupoid 2-cocycle known as the twist of the Drinfeld double, as recalled for instance on the first page of [42]:

$$
\left(\tau_{\mathbf{B} \mathbb{Z}} \alpha\right):\left(x \xrightarrow{g} g x g^{-1} \xrightarrow{h}(h g) x(h g)^{-1}\right) \mapsto \frac{\alpha(x, g, h) \alpha\left(g, h,(h g) x(h g)^{-1}\right)}{\alpha\left(h, g x g^{-1}, g\right)} .
$$

Proof. According to definition A. 13 the transgressed functor is obtained on 2-cells as the composition of $\omega$-anafunctors $\mathbf{B Z} \stackrel{(x, g,)}{\longrightarrow} \mathbf{B} G \xrightarrow{\alpha}>\mathbf{B}^{3} U(1)$, given by

where $(x, g, h)$ denotes a 2 -cell in $\Lambda G$

which comes from a prism

in $\mathbf{B} G$. The 2-cocycle $\tau_{\mathbf{B} \mathbb{Z}} \alpha$ evidently sends this to the evaluation of $\alpha$ on a 3 -morphism in the cover $Y$ filling this prism. One representation of such a 3 -morphism, going from the back and rear to the top and front of this prism, is

Here the first step follows by 2-dimensional whiskering of the standard 3-morphism:

This manifestly yields the cocycle as claimed.

### 6.2.4 The Drinfeld double modular tensor category from DW bibranes

Let again $\rho: \mathbf{B}^{2} U(1) \rightarrow 2$ Vect be the representation of $\mathbf{B} U(1)$ from section 6.1 .3 and let $\tau_{\mathbf{B} \mathbb{Z}} \alpha: \Lambda G \rightarrow \mathbf{B}^{2} U(1)$ be the 2-cocycle obtained in section 6.2.3 from transgression of a Dijkgraaf-Witten line 3 -bundle on $\mathbf{B} G$ and consider the the $\rho$-associated 2 -vector bundle $\rho \circ \tau_{\mathbf{B} \mathbb{Z}} \alpha$ corresponding to that. Its sections according to definition 3.25 form a category $\Gamma\left(\tau_{\mathbf{B} \mathbb{Z}} \alpha\right)$.

Corollary 6.2 The category $\Gamma\left(\tau_{\mathbf{B} \mathbb{Z}} \alpha\right)$ is canonically isomorphic to the representation category of the $\alpha$ twisted Drinfeld double of $G$.

Proof. Follows by inspection of our definition of sections applied to this case and using the relation established in 6.2 .3 between nonabelian cocycles and the ordinary appearance of the Drinfeld double in the literature.

In the case that $\alpha$ is trivial, the representation category of the twisted Drinfeld double is well known to be a modular tensor category. We now show how the fusion tensor product on this category is reproduced from a monoid of bibranes on $\Lambda G$.

Consider any 2-group $\mathbf{B} G_{2}:=\left(G \ltimes H \underset{(\mathrm{Id} \cdot \delta)}{\stackrel{p_{1}}{\longrightarrow}} G \longrightarrow \mathrm{pt}\right)$.
Pullback to the single object of $\mathbf{B E} \mathbb{Z}$ yields a canonical morphism from the disk-space $D G_{2}:=\operatorname{hom}\left(\mathbf{B E Z}, \mathbf{B} G_{2}\right)$ to $\mathbf{B} G, p: D G_{2} \rightarrow \mathbf{B} G$ which inherits from the 2-group the structure of a category internal to groupoids in that on the span $\quad D G_{2} \quad$ there is induced the structure of a monad from the horizontal compo-

sition in $G_{2}$. Notice that $D G_{2}$ is very similar to but in general slightly different from the action groupoid $H / / G$ obtained from the canonical action of $G$ on $H$ in a 2-group. Both coinide in the special case that $G_{2}=\mathbf{E} G$, so that $H=G$. In this case the morphism $p$ exhibts $D G_{2}$ as the action groupoid (as in section 6.1.1) of $G$ acting on itself by the adjoint action.

For $\mathbf{B} G \rightarrow 2$ Vect the trivial gerbe, the transformations $\quad D G_{2} \quad$ are representations of $D G_{2}$ on

vector spaces. In the case that $H=G$ and the boundary map is the identity we have $D G_{2}=\Lambda G$, so that, by the above, bibranes on $D G_{2}$ become representations of $\Lambda G$.

One checks in this case that the fusion product of bibranes using the internal category structure on $D G_{2}$ according to 5.8 does reproduce the familiar fusion tensor product on representations of $\Lambda G$, hence of the Drinfeld double.

### 6.2.5 The DW path integral

Let $S_{\text {in }}$ and $S_{\text {out }}$ be two oriented surfaces and let $V$ be an oriented 3-manifold with boundary $\partial V=S_{\text {in }} \sqcup \bar{S}_{\text {out }}$.
Forming fundamental groupoids yields a co-span

Notice that the space of fields on $V$ in DW theory hom $(\Sigma, \mathbf{B} G)$ is equivalent to the groupoid of $G$-principal bundles on $V$. This implies that pull-push quantum propagation in the sense of section 5.3 reproduces the right DW path integral.

### 6.3 Yetter-Martins-Porter model: target space $\mathbf{B} G_{2}$

The Yetter-Martins-Porter model is a $\sigma$-model with target space $X=\mathbf{B} G$ for $G$ a 2-group.
Here, too, our quantization reproduces the right combinatorial path integral factor [?].

## A $\omega$-Categories and their Homotopy Theory

An $\infty$-category is a combinatorial model for higher directed homotopies, a combinatorial model for a directed space. The fact that it is directed means that not all cells in this space are necessarily reversible. If they are, the $\infty$-category is an $\infty$-groupoid, a combinatorial model for an ordinary space.

There are various definitions of $\infty$-categories and $\infty$-groupoids [21]. Most of them model $\infty$-categories as conglomerates of $n$-dimensional cells of certain shape, for all $n \in \mathbb{N}$, equipped with certain structure and certain properties.

Conglomerates of cells. A "conglomerate of $n$-dimensional cells of certain shape" technically means a presheaf on a category of basic cells.

Simplicial sets and $(\infty, 1)$-categories. The most familiar example is the simplicial category $\Delta$ whose objects are the standard cellular simplices and presheaves on which are simplicial sets. A popular model for $\infty$-groupoids are simplicial sets with the Kan property: Kan complexes. The Kan property can be interpreted as ensuring that for all adjacent simplices in the Kan simplicial set there exists a composite simplex and that for all simplices there exists a reverse simplex. Replacing the Kan property on simplicial sets by a slightly weaker property called the weak Kan property generalizes Kan complexes to a model of $\infty$-categories called weak Kan complexes or quasicategories or $(\infty, 1)$-categories: the weak Kan condition ensures just that for all $n$-simplices for $n \geq 2$ there exists a reverse simplex. A further weakening of the Kan condition such as to ensure only the existence of composites without any restriction on reversibility leads to a definition of weak $\infty$-categories based on simplicial sets with extra properties proposed by Ross Street []. This is very general but also somewhat unwieldy.

Two other basic shapes of relevance besides simplices are globes and cubes.

## Globular sets and $\omega$-categories.

## Cubical sets and $n$-fold categories.

$\infty$-Categories in terms of 1-categories. A general strategy to handle $\infty$-categories in practice is to regard them as categories (i.e. 1-categories) with extra bells and whistles. This notably involves the tools of enriched category theory and of model category theory.

Enriched categories. The definition of a category enriched over a monoidal category $\mathcal{V}[20]$ is like that of an ordinary category, but with the requirement that there is a set of morphisms between any two objects replaced by the requirement that there is an object of $C$ for any two objects. If the enriching category $\mathcal{V}$ is a category of higher structures, such as simplicial sets, $\mathcal{V}$-enriched categories are models for $\infty$-categories. In practice the advantage of conceiving $\infty$-categories as suitably enriched categories is that enriched category theory is a well-developed subject with a supply of powerful general tools.

Model categories. From the modern perspective, a model category (Quillen model category), is the 1categorical truncation of an ( $\infty, 1$ )-category, remembering which of the 1-morphisms retained used to be like isomorphisms, monomorphisms and epimorphisms up to higher coherent cells, in the original ( $\infty, 1$ )-category: in a model category these special 1-morphisms are, respectively, called weak equivalences, cofibrations and fibrations and satisfy a couple of properties.

One says that model categories are presentations of $(\infty, 1)$-categories in that they provide a convenient re-packaging of the information contained in an ( $\infty, 1$ )-category in purely 1-categorical terms. In practical computation the model category structure on a 1-category is in particular used to generalize morphisms between given objects to morphisms between suitable weakly equivalent replacements of these objects.

Our approach. The $\infty$-vector bundles which we want to describe are given by cocycles with values in $\infty$-categories (of models for $\infty$-vector spaces) which are not $\infty$-groupoids and are not $(\infty, 1)$-categories in that in general they have non-reversible cells in all degrees.

Among the simplicial models for $\infty$-categories this would force one to use models such as Street's weak $\infty$-categories. This model, however, we find unwieldy for our applications.

Among the remaining choices of models for $\infty$-categories for our developments in sections 3 and 5 we choose one which combines the "folk" model category structure [14] on $\omega$ Categories with the enrichment of $\omega$ Categories over itself [11]. For most considerations in section 5 and 6 this means effectively that we work in the 1-category $\omega$ Categories while making use of the internal hom-functor and using the freedom to replace $\omega$-categories by weakly equivalent replacements.

For handling $\omega$ Categories the different shapes - globes, simplices, cubes - are useful for different purposes. Globular sets have the simplest boundary structure, simplicial sets provide powerful computational tools, cubical sets provide the important monoidal structure. In the following all three models of shapes are combined: following $[8,11]$ we conceive $\omega$-categories as globular sets for general purposes and make use of their incarnation as cubical sets for describing their biclosed monoidal structure. Moreover, following [38, 8] we use cosimplicial $\omega$-categories such as the orientals to pass between $\omega$ Categories and SimplicialSets, mostly for the purpose of constructing weakly equivalent replacements of $\omega$-categories.

## A. 1 Shapes for $\infty$-cells

Three types of basic shapes are used frequently: globes, simplices and cubes. These are modeled, respectively, by the globular category $G$, the simplicial category $\Delta$ and the cubical category $C$. These three categories have as objects the integers, $n \in \overline{\mathbb{N}}$, thought of as the standard cellular $n$-globe $G^{n}$, the standard cellular $n$-simplex $\Delta^{n}$ and the standard cellular $n$-cube $C^{n}$, respectively. Morphisms are all maps between these standard cellular shapes which respect the cellular structure.

Definition A. 1 (globular category) The globular category $G$ is the category whose objects are the integers $\mathbb{N}$ and whose morphisms are generated from morphisms

$$
\sigma_{n}, \tau_{n}:[n] \rightarrow[n+1]
$$

subject to the relations

for all $n \in \mathbb{N}$.
Definition A. 2 (simplicial category) The simplicial category $\Delta$ is the full subcategory of Categories on categories which are freely generated from connected linear graphs. Equivalently, $\Delta$ is the category with totally ordered finite sets as objects and order-preserving maps as morphisms.

Definition A. 3 (cubical category) The cubical category $C$ is defined ... section 2 of [11]
Definition A. 4 (monoidal structure on the cubical category) section 2 of [11]

## A. $2 \omega$-Categories

Recall the following standard facts:

- The category Sets is symmetric monoidal with respect to the standard cartesian product.
- For $\mathcal{V}$ a symmetric monoidal category, the category $\mathcal{V}$-Cat of $\mathcal{V}$-enriched categories is naturally itself symmetric monoidal.

Definition A. 5 (strict globular n-category, [13]) The category of 0-categories is 0Categories $:=$ Sets. For $n \in \mathbb{N}, n \geq 1$ the category of ("strict, globular") $n$-categories is defined inductively as the category

$$
n \text { Categories }:=(n-1) \text { Categories }- \text { Cat }
$$

of categories enriched over ( $n-1$ ) Categories.
One notices that for all $n \in \mathbb{N}$ there is a canonical inclusion $n$ Categories $\hookrightarrow(n+1)$ Categories.
Definition A. 6 ( $\omega$-category, [39]) The category of $\omega$-categories is the direct limit over this chain of inclusions

$$
\omega \text { Categories }:=\lim _{\rightarrow n \in \mathbb{N}} n \text { Categories }
$$

Unwrapping this definition shows that $\omega$-categories are globular sets equipped with compatible structures of a strict 2-category on all sub-globular sets of length two:

Definition A.7 (globular set) A globular set $S$ is a presheaf on the globular category G, i.e. a functor $S: G^{\mathrm{op}} \rightarrow$ Sets.

We write $S\left([n] \xrightarrow{\sigma_{n}, \tau_{n}}[n+1]\right):=S_{n+1} \xrightarrow{s_{n}, t_{n}} S_{n}$ and call $S_{n}$ the set of $n$-globes, $s_{n}$ the $n$-source map and $t_{n}$ the $\underline{n-\text { target map of } S \text {. The identities } s_{n} \circ s_{n+1}=s_{n} \circ t_{n+1} \overline{\text { and } t_{n} \circ s_{n+1}}=t_{n} \circ t_{n+1} \text {, called the }}$ $\underline{\text { globular identities, }}$, ensure that for all $n, k \in \mathbb{N}$ there are unique maps $S_{n+k} \xrightarrow{s, t} S_{n}$ themselves satisfying analogous globular identities.

Proposition A. 8 ( $\omega$-category, [38]) An $\omega$-category $C$ is a globular set $C: G^{\mathrm{op}} \rightarrow$ Sets equipped for all $n, k \in \mathbb{N}$ the structure of a category extending $C_{n+k} \xrightarrow[t]{\leftrightarrows} C_{n}$ such that this makes for all $n, k, l \in \mathbb{N}$ $C_{n+k+l} \underset{t}{\stackrel{s}{\Longrightarrow}} C_{n+k} \xrightarrow[t]{\stackrel{s}{\Longrightarrow}} C_{n}$ into a strict 2-category.

The elements in $C_{k}$ are called $\underline{k \text {-morphisms. The composition in } C_{n+k} \xrightarrow[t]{\stackrel{s}{\longrightarrow}} C_{n} \text { is called }{ }^{\text {-m }} \text {. }}$ composition of $n+k$-morphisms along $n$-morphisms. A morphism between $\omega$-categories, called an $\underline{\omega}$-functor, is a morphism of the underlying globular sets respecting all the additional structure.

Definition $\mathbf{A .} 9$ (standard globular globes) The globular set $G_{n}$ represented by $n \in \mathbb{N}, G_{n}:=\operatorname{Hom}_{G}(-,[n])$ is the standard globular globe. There is a unique structure of an $\omega$-category on $G_{n}$. This yields co-globular $\omega$-category $G_{\bullet}$, i.e. a functor $G^{\bullet}: G \rightarrow \omega$ Categories.

We also write

- $\emptyset:=: G^{-1}:=: \mathcal{I}^{-1}$ for the $\omega$-category on the empty globular set (the initial object in $\omega$ Categories);
- pt $:=: I:=: \mathcal{I}^{0}:=G^{0}=\{\bullet\}$ for the $\omega$-category with a single object and no nontrivial morphisms (the terminal object in $\omega$ Categories and the tensor unit with respect to the Crans-Gray tensor product $\otimes$ described below);
- $\mathcal{I}:=: \mathcal{I}^{1}:=G^{1}=\{a \longrightarrow b\}$ for the $\omega$-category with two objects and a single nontrivial morphism connecting them.

The first few $n$-globes can be depicted as follows:

## A. $3 \omega$-Groupoids

... $\omega$-groupoids and crossed complexes...

## A. 4 Cosimplicial $\omega$-categories

We can translate back and forth between simplicial sets and $\omega$-categories by means of a fixed cosimplicial $\omega$-categeory, i.e. a functor $O: \Delta \rightarrow \omega$ Categories from the simplicial category $\Delta$ : from any such we obtain an $\omega$-nerve functor $N: \omega$ Categories $\rightarrow$ SimplicialSets by

$$
N(C): \Delta^{\mathrm{op}} \xrightarrow{O^{\mathrm{op}}} \omega \text { Categories }^{\mathrm{op}} \xrightarrow{\operatorname{Hom}(-, C)} \text { Sets }
$$

and its left adjoint $F$ : SimplicialSets $\rightarrow \omega$ Categories given by the coend formula

$$
F\left(S^{\bullet}\right):=\int^{[n] \in \Delta} S^{n} \cdot O([n])
$$

Ross Street defined such a cosimplicial $\omega$-category called the orientals [38], for which $O([n])$ is the $\omega$ category free on a single $n$-morphism of the shape of an $n$-simplex. To obtain more inverses, we can alternatively use the unorientals, for which $O([n])$ is the $\omega$-category with $n$-objects, with 1-morphisms finite sequences of these objects, 2-morphisms finite sequences of such finite sequences, and so on.

## A. 5 Monoidal biclosed structure on $\omega$ Categories

The category $\omega$ Categories is is equipped with the Crans-Gray tensor product [11], which is the extension to $\omega$-categories of the tensor product on cubical sets which in turn is induced via Day convolution from the addition of natural numbers. This means that the Crans-Gray tensor product is dimension raising in a way analogous to the cartesian product on topological spaces:
for instance the tensor product of the interval $\omega$-category $I=\{a \longrightarrow b\}$ with itself is the $\omega$-category free on a single directed square

Moreover, $\omega$ Categories is biclosed with respect to this monoidal structure.
Definition $\mathbf{A .} 10$ (internal hom) For $\omega$-categories $C$ and $D$ the $\omega$-category $[C, D]$ is given by the globular set $\operatorname{Hom}\left(G_{[-]} \otimes C, D\right): G^{\mathrm{op}} \rightarrow$ Sets on which the composition of $k$-morphisms along an l-morphism is defined as the image of the diagram which glues two standard $k$-globes along a common l-globe

under $\operatorname{Hom}\left(G_{[-]} \otimes C, D\right)$ :

Remarks. Notice that everything in this definition works by abstract nonsense - for instance that the contravariant Hom takes colimits to limits - except the existence of the maps $c_{k, l}$, which encodes genuine information about pasting of standard globes [10]. For instance $G_{2} \sqcup_{G_{0}} G_{2}=\{$ while $G_{2} \sqcup_{G_{1}} G_{2}=\{a \xrightarrow{\downarrow} b\}$, where the right sides denote the free $\omega$-categories on the indicated
pasting diagram [10].
Proposition A. 11 For every $C \in \omega$ Categories this extends to a functor $[C,-]: \omega$ Categories $\rightarrow \omega$ Categories which is right adjoint to $-\otimes C: \omega$ Categories $\rightarrow \omega$ Categories.

Of particular interest to us are the internal hom- $\omega$-categories of the form $A^{\mathcal{I}}:=[\mathcal{I}, A]$ which satisfy
$\operatorname{Hom}(I \otimes X, A) \simeq \operatorname{Hom}\left(X, A^{\mathcal{I}}\right)$, where the set in question here is the set of lax transformations

## A. 6 Model structure on $\omega$ Categories

That the 1-category $\omega$ Categories is really an $\infty$-structure itself is remembered by a model category structure carried by it, due to [14], with respect to which the acyclic fibrations or hypercovers $f: C \xrightarrow{\simeq} D$ are those $\omega$-functors which are $k$-surjective for all $k \in \mathbb{N}$, meaning that the universal dashed morphism in

is epi, for all $k$. The weak equivalences $f: C \xrightarrow{\simeq} D$ are those $\omega$-functors where these dashed morphisms become epi after projecting onto $\omega$-equivalence classes of $(k+1)$-morphisms.

Using this we define an $\omega$-anafunctor from an $\omega$-category $X$ to an $\omega$-category $A$ to be a span

$$
(g: X \longrightarrow \mid \rightarrow A):=\underset{\substack{\hat{X} \\ \\ X}}{\stackrel{g}{\longrightarrow} A}
$$

whose left leg is a hypercover. (This terminology follows [22, 5].) One finds [7] that in the context of $\omega$ Groupoids such $\omega$-anafunctors represent morphisms in the homotopy category $[g] \in \operatorname{Ho}(X, A)$ which allows us to regard $g$ as a cocycle in nonabelian cohomology on the $\omega$-groupoid $X$ with coefficients in the $\omega$-groupoid $A$. Cocycles are regarded as distinct only up to refinements of their covers. This makes their composition by pullbacks

well defined (noticing that acyclic fibrations are closed under pullback) and associative.

Definition A. 12 We write Ho for the corresponding category of $\omega$-anafunctors,

$$
\operatorname{Ho}(C, D):=\operatorname{colim}_{\hat{C} \in \operatorname{Hypercovers}(C)} \operatorname{Hom}(\hat{C}, D) .
$$

(This is to be contrasted with the true homotopy category Ho, which is obtained by further dividing out homotopies.)

While cocycles in nonabelin cohomology are morphisms in Ho, coboundaries should be morphisms between these morphisms. Hence Ho is to be thought of as enriched over $\omega$ Categories.

Definition A. 13 Define a functor hom : $\mathbf{H o}^{\mathrm{op}} \times \mathbf{H o} \rightarrow \omega$ Categories by $\left.\operatorname{hom}(C, D):=F(\operatorname{Hom}(C \otimes O([\bullet]), D))\right)$.
